1. Purpose and scope

The engineering practices every engineer and agent follows on a Salesforce exit, and the industry references behind them. We check them automatically on every change. How we apply them to this module is in the HLD and LLD.

2. Principles

Principle	Practice
Single responsibility	One agent, one job, one output folder
One source of truth	A versioned model drives everything we generate; nobody edits generated output by hand
Deterministic and repeatable	The same input always gives the same output; CI regenerates and fails on any difference
Least privilege	Read-only access to the source; the narrowest role for every user, service and pipeline
Evidence over assertion	Every claim (a count, a match, a pass) comes from a report that anyone can re-run

3. Secure development

Risk area	Practice
Broken access control	Enforce access where the data lives, not only in screens; test each role
Injection	Parameterised queries only; no SQL built from user input
Secrets	Never in source; held in a vault, referenced by managed identity, scanned on every change
Software supply chain	Pinned dependency versions, lock files committed, pipeline actions pinned, audit on every build
Integrity	Protected main branch; nothing merges without review and passing checks
Logging and monitoring	Every agent run, approval and deployment is recorded with who and when

4. Database engineering

- Schema changes are numbered scripts, applied in order, each with one owner, rebuildable from the model
- Business rules as constraints, so every client of the data gets the same rule
- Names come from the business vocabulary, in one consistent case style
- Every change is backward compatible during a migration window (expand, then contract)

5. Testing

- The source system is the reference: expected values come from it (golden-master testing)
- Every behaviour has a test; nothing is released with a failing test
- Tests are code, versioned with what they test, and run in CI on every change
- Security has its own tests: each role tries what it may and may not do

6. Model-drafted code and review

Guardrail	How we enforce it
Model output is a proposal	An engineer reviews and approves it before it merges
The model is never in the runtime path	A language model is used only at build time; the running system does not depend on one
Each agent stays in its lane	Each agent may only write to its own folder
Human approval at every phase	Approve, edit or return at each gate, fully audited
No secrets or personal data in prompts	Inputs are masked and scanned automatically

7. Source control and delivery

- Trunk-based development with short-lived branches and pull-request review
- Infrastructure as code for every environment; no manual changes in the portal
- The pipeline deploys with a federated identity, not a stored password
- Every release is traceable to a commit, a review and a test report

8. Documentation

- Architecture documents follow arc42, with C4 diagrams for context and containers
- Every significant decision has an architecture decision record (ADR)
- Documents are generated from the source, so they never go out of date
